Key Behavioral Mechanics:

- * **ADX Filter Efficiency:** The `regimeAdxThreshold`` of `25`` successfully quarantines the engine during aggressive breakout trends. The high win rate confirms that execution is restricted to low-trending, bracketed market structures ($ADX < 25$).
- * **Time-Decay Dependency** (`maxTicksInTrade: 120``): The system enforces strict temporal hygiene. By auto-liquidating trades that stagnate past 120 ticks, the engine avoids capital lockup in degrading or low-momentum regimes.
- * **Confluence Calibration:** A `minConfluenceScore`` of `3`` prevents over-trading, ensuring that entries require simultaneous verification (e.g., RSI extreme + BB touch + Volume/ATR confirmation).

3. Calibrated Parameter Recommendations

To protect the system from regime shifts and improve capitalization without degrading the mathematical edge, implement the following adjustments:

```

```json
{
 "currentConfig": {
 "rsiOversoldThreshold": 30,
 "rsiOverboughtThreshold": 70,
 "bbPeriod": 20,
 "bbStd": 2.25,
 "maxTicksInTrade": 120,
 "minConfluenceScore": 3,
 "atrStopMultiplier": 3.15,
 "regimeAdxThreshold": 25
 },
 "calibratedConfig": {
 "rsiOversoldThreshold": 25,
 "rsiOverboughtThreshold": 75,
 "bbPeriod": 20,
 "bbStd": 2.50,
 "maxTicksInTrade": 90,
 "minConfluenceScore": 4,
 "atrStopMultiplier": 2.75,
 "regimeAdxThreshold": 20
 }
}

```

## # Rationale for Calibrated Adjustments:

### 1. **RSI Extremes** (`30/70` !` 25/75``):

- \* **Objective:** Filter out premature entries during strong momentum runs.

Tightening the boundaries reduces trade frequency but increases the probability of immediate mean-reversion at absolute exhaustion points.

2. **Bollinger Band Standard Deviation (2.25' 2.50):**

\* **Objective:** Capture wider premium swings. Moving the entry threshold to  $2.5\sigma$  targets rarer, highly profitable liquidity sweeps, improving the low \$0.79 average trade yield.

3. **ATR Stop Multiplier (3.15' 2.75):**

\* **Objective:** Truncate the negative tail-risk. A  $3.15 \times \text{ATR}$  stop is too loose for micro-scalps. Tightening to  $2.75 \times \text{ATR}$  mitigates heavy drawdown events when a range breaks, protecting the high win-rate structure from catastrophic loss distribution.

4. **Regime ADX Threshold (25' 20):**

\* **Objective:** Strict trend avoidance. An ADX of 25 can already support a sustained breakout. Lowering the threshold to 20 ensures the algorithm is only active in true sideways, low-energy distributions.
